

Abundance-weighted metabolic potential of group-dereplicated K08356 MAGs

49 K08356 sequences / 48 unique MAGs / 56 samples; clades 3/7/19/20; descriptive group-reference TPM analysis

Fill: TPM-weighted mean metabolic score across detected host MAG abundance. Size: percentage of samples in a habitat with TPM >0 for at least one host MAG passing the legacy >=50% partial-reconstruction threshold. Arsenic rows use independent non-focal binary markers; other rows use the predefined legacy gene-set coverage. S1_9-12_bin1 contributes to Clades 1 and 3, so clade categories are non-exclusive; an exclusion sensitivity table is provided. Important: Clades 1-3 mix target MAGs quantified in different background references (315/128/252/156 MAGs) and are descriptive. All 20 Clade 4 MAGs use the same IS reference across 56 samples, so its companion habitat comparison is reference-consistent but still lacks station/depth adjustment. Do not use this plot alone to claim a habitat-driven mechanism or spatial heterogeneity. IS, incipient seep; AS, active seep; ES, extinct seep; NS, non-seep background.
